Scientific Explorers Space Scientists Fly 600 Million Kilometers to Land on Europa in a High-Speed Heavy-Load Rocket

木卫二与地球的距离随公转轨道动态变化，平均距离约为 6.84 亿公里。- 最近距离：约 6.28 亿公里，出现在地球与木星位于太阳同侧时。- 最远距离：约 9 亿公里以上，出现在两者位于太阳两侧时。- 其他数据：媒体常引用的 4 亿英里（约 6.44 亿公里）或 6 亿公里均为不同时期的近似值。木卫二绕木星公转，其地心距离主要取决于木星与地球的相对位置，因此数值会在一定范围内波动。

按“近期可登陆中期可登陆远期宜居候选”排序，人类最可能率先登陆并建立基地的天体是：月球火星木卫二土卫六；系外行星暂时只有远程观测，无登陆可行性。一、月球（最优先，2030年前可载人登陆）- 基本参数：地球唯一卫星，距地球约38万公里；直径约地球1/4，重力约地球1/6；无大气、无磁场，昼夜温差约

**** -173°C~127°C****。- 为何最优先- 距离极近：3天可达，往返成本最低、风险最小。- 资源可用：土壤含氦-3（可控核聚变燃料）、氧、铁、铝；极地永久阴影区有水冰。- 战略跳板：低重力可作为深空探测的燃料补给与组装基地。- 登陆进展：NASA“阿尔忒弥斯”计划2025-2026年载人登月；中国2030年前载人登月，规划月球科研站。二、火星（近期首选行星，2030-2040年载人登陆）- 基本参数：类地行星，距地球最近约5500万公里；直径约地球1/2，重力约地球38%；自转24.6小时，有四季；大气极稀薄（约地球0.6%），以CO₂为主；表面平均约**** -60°C****，有氧化铁荒漠、干涸河床、极地冰盖。- 登陆核心优势- 环境最像地球：昼夜、季节接近，低重力更易适应。- 水冰丰富：极地冰盖、地下冻土含大量水，可饮用、制氧、制燃料。- 可改造潜力：大气CO₂可用于温室改造，提升温度与气压。- 主要障碍：辐射强、土壤含高氯酸盐有毒、极端低温、大气过薄无法呼吸。- 登陆进展：NASA目标2033-2035年；SpaceX“星舰”2029年前；中国2033-2035年无人采样返回，2040年前载人登陆。三、木卫二（欧罗巴，中期可登陆，2040-2050年后）- 基本参数：木星四颗伽利略卫星之一，距地球约6.3亿公里；直径约3100公里，重力约地球13%；表面为数公里厚冰壳，冰下是全球液态海洋（水量约地球2倍）；表面约**** -170°C****，有稀薄氧大气。- 登陆核心价值- 冰下海洋：太阳系最可能存在地外生命的地方，潮汐加热可能形成热液喷口。- 水资源巨量：冰与海水可直接供给生命与燃料。- 主要障碍：距离远（单程

需6-8年)、木星强辐射、冰面崎岖且可能有喷流、登陆后需钻冰探测海洋。- 探测进展: NASA“欧罗巴快船”2024年发射, 2030年抵达; 后续规划冰面着陆器与钻冰机器人。四、土卫六(泰坦, 远期可登陆, 2050年后)- 基本参数: 土星最大卫星, 距地球约12.7亿公里; 直径约5150公里, 重力约地球14%; 太阳系唯一厚大气卫星(气压约地球1.5倍), 95%氮气; 表面约**-179℃**, 有液态甲烷/乙烷湖泊与河流, 固态水冰为基岩。- 登陆核心优势- 大气防护: 厚氮大气可挡辐射, 有天然温室效应。- 完整循环: 甲烷循环类似地球水循环, 碳氢化合物可作能源与化工原料。- 资源多样: 水冰、甲烷、氮均可利用。- 主要障碍: 距离极远(单程7-10年)、极低温、大气浓雾影响观测、甲烷易燃易爆。- 探测进展: 卡西尼号已证实甲烷海洋; NASA规划“蜻蜓”号无人机2027年发射, 2034年抵达; 载人登陆预计2050年后。五、系外宜居候选(仅远程观测, 无登陆可能)- Gliese 832c: 距地球16光年, 位于宜居带, 质量约地球5倍, 可能有岩石表面与液态水。- HD 137010 b: 距地球146光年, 大小与地球接近, 公转355天, 位于宜居带, 被称为“冰冻地球”。- 开普勒-186f: 距地球500光年, 岩石行星, 位于宜居带, 大小接近地球。- 现状: 均距离过远(光年尺度), 现有技术无法实现载人登陆, 仅能通过望远镜与探测器远程研究。总结: 登陆优先级与时间线1. 月球: 2025-2030年, 必登, 科研与基地首选。2. 火星: 2030-2040年, 载人登陆, 人类第二家园核心目标。3. 木卫二: 2040-2050年, 无人探测优先, 生命探测核心。4. 土卫六: 2050年后, 远期科研与资源开发。5. 系外行星: 百年内无登陆可行性。

原文标题

Scientific Explorers Space Scientists Fly 600 Million Kilometers to Land on Europa in a High-Speed Heavy-Load Rocket

1. 英语(原版)

Scientific Explorers and Aerospace Scientists Travel 600 Million Kilometers aboard a High-Speed Heavy-Lift Rocket to Land on Europa.

The distance between Europa and Earth varies dynamically with their orbital revolution, with an average distance of about 684 million kilometers.

- Closest distance: Approximately 628 million kilometers, occurring when Earth and Jupiter are on the same side of the Sun.

- Farthest distance: Over 900 million kilometers, occurring when the two are on opposite sides of the Sun.

- Other data: The commonly cited figure of 400 million miles (about 644 million kilometers) or 600 million kilometers are approximate values for different orbital periods.

Europa orbits Jupiter, and its geocentric distance mainly depends on the relative position of Jupiter and Earth, so the value fluctuates within a certain range.

Ranked by near-term landing feasible / mid-term landing feasible / long-term habitable candidate, the celestial bodies most likely for humanity to land on and build bases first are: the Moon, Mars, Europa, Titan. Exoplanets can only be observed remotely for now, with no feasibility for landing.

I. The Moon (Highest Priority, Manned Landing Before 2030)

- Basic parameters: Earth's only natural satellite, about 380,000 kilometers from Earth; diameter roughly 1/4 of Earth's; gravity about 1/6 of Earth's; no atmosphere or magnetic field; temperature range $-173^{\circ}\text{C} \sim 127^{\circ}\text{C}$.

- Reasons for top priority- Extremely close distance: Reachable in 3 days, lowest round-trip cost and minimal risk.

- Available resources: Lunar soil contains Helium-3 (fusion fuel), oxygen, iron and aluminum; water ice exists in polar permanent shadow regions.

- Strategic springboard: Low gravity serves as a refueling and assembly base for deep space exploration.

- Landing progress: NASA Artemis Program plans manned lunar landing in 2025–2026; China aims for manned lunar landing before 2030 and plans a lunar research station.

II. Mars (Primary Near-Term Planet, Manned Landing 2030–2040)

- Basic parameters: Terrestrial planet; closest distance to Earth about 55 million kilometers; diameter nearly half of Earth's; gravity 38% of Earth's; 24.6-hour rotation with four seasons; extremely thin atmosphere (0.6% of Earth's) dominated by CO_2 ; average surface temperature -60°C , featuring iron oxide deserts, dried river beds and polar ice caps.

- Core advantages for landing- Most Earth-like environment: Similar day-night cycle and seasons; low gravity easy to adapt to.

- Abundant water ice: Polar ice caps and underground permafrost hold massive water for drinking, oxygen production and fuel synthesis.

- Terraforming potential: Atmospheric CO_2 can be used for greenhouse transformation to raise temperature and air pressure.

- Major obstacles: Intense cosmic radiation, perchlorate-toxic soil, extreme low temperature, too thin atmosphere for breathing.

- Landing progress: NASA targets 2033–2035; SpaceX Starship before 2029; China plans unmanned sample return 2033–2035 and manned landing before 2040.

III. Europa (Mid-Term Landing, Post 2040–2050)

- Basic parameters: One of Jupiter's four Galilean moons; about 630 million kilometers from Earth; diameter around 3,100 km; gravity 13% of Earth's; surface covered by several-kilometer-thick ice crust, hiding a global subsurface liquid ocean (twice Earth's total water volume); surface temperature -170°C with a tenuous oxygen atmosphere.
- Core exploration value- Subsurface ocean: The most promising place for extraterrestrial life in the Solar System; tidal heating may create hydrothermal vents.
- Massive water resources: Ice and seawater support life survival and fuel production directly.
- Major obstacles: Extreme distance (6–8 years one-way), intense Jovian radiation, rugged icy terrain and possible water plumes, requiring ice-drilling missions to explore the subsurface ocean after landing.
- Exploration progress: NASA Europa Clipper launched in 2024, arriving at Jupiter in 2030; follow-up plans include surface landers and ice-drilling robots.

IV. Titan (Long-Term Landing, Post 2050)

- Basic parameters: Saturn's largest moon; about 1.27 billion kilometers from Earth; diameter around 5,150 km; gravity 14% of Earth's; the only Solar System moon with a dense atmosphere (1.5 times Earth's air pressure) composed of 95% nitrogen; surface temperature -179°C, with liquid methane/ethane lakes and rivers, and solid water ice as bedrock.
- Core advantages for landing- Atmospheric shielding: Thick nitrogen atmosphere blocks cosmic radiation with natural greenhouse effect.
- Complete cycle system: Methane cycle analogous to Earth's water cycle; hydrocarbons usable as energy and chemical raw materials.
- Diverse resources: Water ice, methane and nitrogen all exploitable.
- Major obstacles: Ultra-long distance (7–10 years one-way), ultra-low temperature, dense atmospheric fog hindering observation, flammable and explosive methane.
- Exploration progress: Cassini mission confirmed methane seas; NASA Dragonfly drone scheduled for 2027 launch, arriving in 2034; manned landing expected after 2050.

V. Exoplanet Habitable Candidates (Only Remote Observation, No Landing Feasibility)

- Gliese 832c: 16 light-years from Earth, located in the habitable zone, 5 times Earth's mass, likely with rocky surface and liquid

water.

- HD 137010 b: 146 light-years from Earth, Earth-sized, 355-day orbital period in the habitable zone, known as the "Frozen Earth".

- Kepler-186f: 500 light-years from Earth, rocky exoplanet in the habitable zone with Earth-like size.

- Current status: All are light-years away; current technology cannot achieve manned landing, only remote research via telescopes and probes.

Summary: Landing Priority & Timeline

1. The Moon: 2025–2030, mandatory landing, top choice for scientific research and base construction.

2. Mars: 2030–2040, manned landing, core target for humanity's second home.

3. Europa: 2040–2050, priority for unmanned exploration, core mission for extraterrestrial life detection.

4. Titan: Post 2050, long-term scientific research and resource development.

5. Exoplanets: No manned landing feasibility within a century.

2. 法语

Les explorateurs scientifiques et chercheurs spatiaux parcourent 600 millions de kilomètres à bord d'une fusée à grande vitesse et à forte charge utile pour atterrir sur Europe.

La distance entre Europe et la Terre varie dynamiquement selon leurs orbites de révolution, avec une distance moyenne d'environ 684 millions de kilomètres.

- Distance minimale : environ 628 millions de kilomètres, lorsque la Terre et Jupiter se trouvent du même côté du Soleil.

- Distance maximale : plus de 900 millions de kilomètres, lorsque les deux astres sont de part et d'autre du Soleil.

- Autres données : la valeur souvent citée de 400 millions de miles (environ 644 millions de kilomètres) ou 600 millions de kilomètres sont des approximations selon les périodes orbitales.

Europe orbite autour de Jupiter ; sa distance à la Terre dépend principalement de la position relative de Jupiter et de la Terre, sa valeur fluctue donc dans une fourchette donnée.

Classés par accessibilité à court terme / à moyen terme / candidature habitable à long terme, les corps célestes les plus susceptibles d'être explorés et colonisés en premier sont : la Lune, Mars, Europe, Titan. Les exoplanètes ne peuvent actuellement être qu'observées à distance, sans possibilité d'atterrissage.
